

Road Needs Study Report - 2019 Township of Hamilton D.M. Wills Project No.19-4705

# D.M. Wills Associates Limited

PARTNERS IN ENGINEERING Peterborough

March 2020 Prepared for: Township of Hamilton

# **Executive Summary**

The Township of Hamilton (Township) retained the services of D.M. Wills Associates Limited (Wills) to undertake a review of the Township's existing road network, and assess its physical condition as well as confirm various road attributes. Data collected during the field review was used to develop a prioritized listing of the road network needs, the results of which are documented in this report.

Additionally, Wills inventoried and mapped the Township's guiderail assets. A memo summarizing activities undertaken for the guide rail inventory is included as an appendix of this report.

The Township's road infrastructure system spans a total of 299 km primarily within a rural setting, with small areas of urban and semi-urban development. The road network includes surfaces ranging from gravel to hot mix pavement (asphalt). The Township has approximately 31 km of gravel roads, 145 km of surface treated roads (low class bituminous (LCB) and intermediate class bituminous (ICB)), and 123 km of hot mix asphalt paved roads (high class bituminous (HCB)).

Two (2) primary indicators of the relative health of a road are the structural adequacy and surface condition ratings. The current average structural adequacy rating for the Township's road network is 14.8/20. The current average surface condition rating for the Township's road network is 7.7/10.

# 6.7% (20 km) of the road network has a Structural "NOW" need, 17.7% (53 km) has a Structural "1-5" year need, and 17.0% (51 km) of the road network has a Structural "6-10" year need.

It should be noted that a structural "NOW" need does not explicitly mean that work must be undertaken on the road immediately (although this may be so in some cases). A structural "NOW" need means that a significant portion of the road is showing distress and requires significant intervention i.e. reconstruction or major rehabilitation to renew its service life. A structural "1-5" year need is expected to become a "NOW" need in the next five years, and a "6-10" year need is expected to become a "NOW" need in the next 10 years should no intervention treatments take place.

#### Resurfacing

In addition to addressing currently deficient roads (i.e. capital reconstruction), a dedicated preservation management approach is required, <u>and perhaps even more</u> <u>important</u>, to "keep the good roads good"; the fundamental principle being that it costs much less to maintain a good road than it does to let it fail and then reconstruct it, from a life cycle cost perspective. Ultimately, the goal of preservation management is to extend the useful life of a road and road network, maximizing the Township's investment over the road life-cycle.

Roads with a structural adequacy of 12/20 or greater are included as candidates for potential resurfacing. Preliminary recommendations and prioritization for road resurfacing are based on condition rating and traffic demands on each road section, as per the Inventory Manual. A road with higher traffic volumes and fair structural adequacy is given priority over a road with moderate traffic and good structural adequacy score, in an attempt to intervene and extend the life of the road before it deteriorates to a level that can no longer be resurfaced (i.e. more expensive reconstruction is required). Specific resurfacing treatment recommendations must be assessed through further field investigation and detail design effort, prior to selecting and implementing the resurfacing strategy.

Based on typical degradation rates for gravel roads, surface treatment, and hot mix, a resurfacing program and related budget is recommended as follows:

#### Hot Mix Paved Roads:

- 122.5 km of paved roads (HCB).
- Degradation rate 0.25 / year (rating drops from 10 to 5, over a 20-year period).
- Annual resurfacing 6.1 km / year.
- Annual budget \$1,774,600: (6.1 km / year x \$143,000 / lane km RMP1 x 2 lanes).

#### Surface Treated Roads:

- 145.5 km of surface treated roads (LCB & ICB).
- Degradation rate 0.625 / year (rating drops from 10 to 5, over a 7-year period).
- Annual resurfacing 20.8 km / year.
- Annual budget \$436,800 (20.8 km / year x \$21,000 / km \$T1).

Gravel roads require regular maintenance. Maintenance includes regular grading and reapplication of new gravel. Typically, gravel roads should be resurfaced on a 3-5 year cycle.

#### <u>Gravel Roads:</u>

- 31.4 km of earth / gravel roads.
- 75 mm gravel every 3 years.
- Annual gravelling of 10.5 km.
- Granular A (\$20,000 / km).
- Annual budget \$210,000 (10.5 km / year x \$20,000 G) \*\*.

\*\* Cost based on supply and application of gravel by external forces.

# The total resurfacing program, (hot mix, surface treatment and gravel) is estimated at \$2,391,400 per year.

#### Preservation Management

Preservation techniques seal the surface as to prevent water infiltration into the granular base. Route and Seal is used on HCB pavements to seal individual cracks. Slurry Seal / Microsurfacing is used on LCB and HCB pavements to seal large areas, although wide / active cracks will reflect through the treatment. An annual preservation management budget has been estimated as follows:

#### <u>Cracksealing</u>

- 122.5 km of paved roads (HCB).
- Assume that cracksealing will be applied, on average, once per resurfacing cycle.
- Annual cracksealing of 6.1 km / year
- Annual budget \$24,400 (6.1 km x \$4,000 / km Cracksealing).

#### <u>Slurry Seal / Microsurfacing</u>

- 122.5 km of paved roads (HCB).
- 145.5 km of surface treated roads (LCB & ICB).
- Assume that slurry seal / microsurfacing will be applied, on average, once per resurfacing cycle.
- 26.9 km of road to preserve per year (6.1 km HCB and 20.8 km of LCB).
- Annual budget \$570,470 (26.9 km x \$20,000 / km Slurry Sealing / Microsurfacing).

Further to the recommendations above with respect to resurfacing, it is also recommended that regular maintenance in the form of roadside ditch cleanout and clearing be undertaken as a critical component to preservation management in order to extend the useful service life of the existing roads.

#### Capital Improvements

Preliminary recommendations and prioritization for planned capital improvements i.e. reconstruction, have been developed based on the condition rating and traffic demands on each road section, as per the Inventory Manual. Those roads identified as having a "NOW" or 1 - 5 year need have been included in the capital improvement plan for reconstruction.

A total length of 73.3 km of roads were identified as having structural needs in the "NOW," or 1 - 5 year periods. The estimated cost to improve these roads is approximately \$ 12.5 M.

A fully funded 10 year plan following the recommendations in this report includes \$2.4M/year for resurfacing needs and \$12.5M (\$1.3M/year) for the capital needs over ten years. Funding recommendations can be visualized in the graphic below.

Given that 75% of Hamilton's Road network has a structural adequacy of 12 or higher, Wills recommends that priority should be given to resurfacing and preservation over capital needs should funding fall short of ideal levels.

# 1.0 Purpose, Background and Study Method

#### 1.1 Purpose

The purpose of the 2019 Road Needs Study Report is to update the current road inventory and road condition assessments within the Township of Hamilton (Township). Using this information, a prioritized listing of the road network needs is developed. The information derived from the study and documented in this report will provide assistance to the Township for developing and executing a planned road maintenance and improvement program.

The Township retained the services of D.M. Wills Associates Limited (Wills) to undertake a review of the existing road network, and assess its physical condition as well as confirm various attributes. Data collected as a result of the field review is used to develop a prioritized listing of the road network needs, the results of which are documented in this report.

#### 1.2 Background

The Township of Hamilton is located in the County of Northumberland, between Rice Lake and Cobourg. The Township is largely rural with some scattered urban / semiurban developments.

This Road Needs Study was completed to inventory and document the Township's existing road assets. This current study (2019) utilizes sectioning as per the last report. The GIS mapping from the County has been updated to harmonize with sectioning used in this report.

#### 1.3 Study Objectives

Based on discussion with Township staff, the following study objectives were identified:

- Provide a current inventory and value of the Township's roads, assess road conditions and needs, and develop a priority listing for construction needs and improvements.
- Provide a prioritized list of capital projects for the Township to invest in.

To ensure compliance with the latest Ministry of Transportation (MTO) guidelines, the inventories were completed in accordance with the most current edition of the Inventory Manual for Municipal Roads.

#### 1.4 Study Methodology

The procedure utilized to complete the study was in accordance with the Ministry of Transportation's Inventory Manual for Municipal Roads (February 1991).

Additionally, field reviews for the purpose of Pavement Condition Index (PCI) were undertaken in accordance with:

- MTO Manual for Condition Rating of Flexible Pavements, SP-024.
- MTO Manual for Condition Rating of Surface-Treated Roads, SP-021.

There are two (2) key observations when using PCI methods: The Ride Condition Rating (RCR), and the Distress Manifestation Index (DMI). RCR is a subjective measurement of how smooth a travelled surface is, rated from 0 to 10, with 10 representing excellent, new surfaces, and 0 representing an extremely rough, impassible road. DMI aggregates various forms of visible pavement distress into a rating from 0 to 10, with 10 representing a new surface and 0 representing a destroyed surface.

RCR and DMI are rated strictly independently. A rough road may have relatively few visible distresses while a fairly smooth road may display many distresses. In general, rough roads display associated visible distresses.

The combined approach facilitates comparing all the Township's roads, as the Inventory Manual prescribes the same rating system regardless of surface type, while also providing detailed descriptions of the types of distress encountered on surfaces as per the PCI ratings. This approach is compliant with O. Reg. 588/17. Wills undertook the field study in July of 2019.

During the field study, a visual assessment of the following road characteristics was documented to assess the current adequacy of the road:

- Platform Width (overall width of road).
- Surface Width (width of pavement surface).
- Shoulder Width.
- Surface Type (gravel, low class bituminous, or high class bituminous).
- Drainage Type (open ditches vs. storm sewers etc.).
- Surface Condition (assigned based on Ride Condition Rating for this Study).
- Maintenance Demand.
- Roadside Environment.
- Capacity.
- Alignment.

#### 1.4.1 Critical Deficiencies

Critical deficiencies represent road characteristics that result in increased maintenance costs or lead to an inadequate level of service. Road sections may be assessed as critically deficient if any one (1) of the following characteristics fall below the minimum tolerable standards defined in the MTO Inventory Manual:

- Surface type
   Insufficient surface type for traffic volumes.
- Surface width
   Insufficient width of the road surface
   excluding the shoulders.
- Capacity
   Inability of the road to accommodate traffic volumes at peak periods.
- Structural Adequacy Inability of the road base to support vehicular traffic.
- Drainage
   Increased frequency of flooding or excessive
   maintenance effort required to prevent flooding.

Critically deficient roads have generally reached the end of their service life and /or require major work to improve e.g. widening or new surface type. As such, reconstruction is generally required.

#### <u>Surface Type</u>

The following parameters were used to assess the adequacy of the road surface type. Road sections with traffic volumes (AADT) in excess of the Minimum Tolerable values for Earth and Gravel in **Table 1**, were noted as critically deficient triggering a "NOW" surface type need as per the Inventory Manual Method.

#### Table 1 – Surface Type by Annual Average Daily Traffic (AADT)

	AADT							
Surface Type	Inventor	y Manual	MTO Pavement Design and Rehabilitation Manual <sup>1</sup>					
	Minimum Tolerable	Design Standard						
Earth (E)	<50	-	-					
Gravel (G)	<400	0-199	0 - 200					
Low Class Bituminous (LCB) / Surface Treatment	-	200-399	200 – 1000 (1000 – 1500 if over Cold Mix)					
High Class Bituminous (HCB) / Hot Mix	-	400+	>1500					

**Table 1** provides further guidance with respect to surface type from both the InventoryManual as well as the MTO Pavement Design and Rehabilitation Manual.

<sup>1</sup> Ministry of Transportation. Pavement Design and Rehabilitation Manual, Second Edition, 2013, Table 3.3.3 Structural Design Guidelines for Flexible Pavement – Secondary Highways

As detailed in **Table 1**, Gravel surfaces are generally considered acceptable for AADT of less than 200 vehicles but may be tolerable up to 400 AADT. Transition to Surface Treatment should be considered above 200 AADT. Gravel road maintenance costs (resurfacing, grading, dust suppression, etc.) versus surface treatment costs are key considerations.

Low Class Bituminous (LCB) i.e. Surface Treatment may be acceptable for traffic volumes between 200 and 1500 AADT. A transition to a Hot Mix or High Class Bituminous surface from Surface Treatment must be considered on a case by case basis. The following factors require consideration:

- Surface Treatment Maintenance Costs.
- Commercial Vehicle Loading.
- Roadside Environment (Urban, Semi-urban, vs. Rural).
- On-street Parking.
- Adjacent Drainage Infrastructure i.e. curb and gutter, catch basins etc.
- Asphalt Availability/Cost.
- Surface/Platform Width.
- Traffic Volume Growth.
- Sub-base Quality.
- Roadbed Frost Susceptibility.
- Future Resurfacing/Rehabilitation Costs.

Vehicle loading is one of the key considerations for pavement design and ultimately the decision between Hot Mix and Surface Treatment. Roads with high levels of commercial traffic require a more substantial pavement structure. The values noted in **Table 1**, for the "MTO Method" are generally reflective of a highway with 10% commercial vehicles. Roads with AADT in excess of 400 vehicles with a good sub-base and commercial vehicles up to 10% may still perform very well with a Surface Treatment. Existing/past performance of a Surface Treatment can be an excellent indicator when considering the upgrade to Hot Mix.

#### Surface Width

Surface widths that fall below minimum tolerable standards, as detailed in the MTO Inventory Manual are noted as critically deficient triggering a "NOW" need. The Minimum Tolerable Surface Widths for Rural roads are included in **Table 2**:

		AADT									
	1-49	40-199	200-399	400-999	1000- 1999	2000- 2999	3000- 3999	4000+			
Road Width (m)	5.0	5.5	5.5	6.0	6.0	6.0	6.5	6.5			

#### Table 2 – Rural Road Surface Width by Annual Average Daily Traffic (AADT)

#### <u>Capacity</u>

An in-depth traffic capacity analysis was not completed as part of the scope of this Road Needs Study. Decisions with respect to expansion of roads should be made within the context of a Transportation Master Plan or Official Plan for the Township.

However, from a general perspective, a two-lane road can typically provide adequate service up to an AADT of approximately 12,000 vehicles. The functionality of a road from a capacity standpoint is of course dependent upon other factors in combination with volume. Adjacent land uses, number of access points i.e. entrances and side roads etc. also have a significant impact on how the road functions.

A rural road with limited entrances and side roads will have a much greater capacity to flow traffic versus an urban street with many entrances and side road intersections. The AADT of 12,000 can be used as a 'rule of thumb' to trigger further analysis on the road capacity and operation. For the purposes of this study, a detailed capacity analysis was not undertaken as part of the scope of work. All roads were assigned to be adequate from a capacity perspective noting that no road section had an AADT greater than 6000 vehicles.

#### Structural Adequacy

In cases where road base or structure is showing distress over more than 20% of the length of the road section, a score between 1 and 7 (out of 20) is assessed and the road section is assigned a "NOW" need and considered Critically Deficient per the Inventory Manual. The structural adequacy rating is often the best indicator of the overall road section's health.

It should be noted that a structural "NOW" need does not explicitly mean that work must be undertaken on the road immediately (although this may be so in some cases). A structural "NOW" need means that a significant portion of the road is showing distress of the road bed and requires significant intervention i.e. reconstruction or major rehabilitation to renew it service life. A structural "1-5" year need is expected to become a "NOW" need in the next five years, and a "6-10" year need is expected to become a "NOW" need in the next 10 years.

#### <u>Drainage</u>

A road section is assessed as a "NOW" need for drainage generally when a road becomes impassible due to water one or more times a year. This information is not readily accessible from inspection. Characteristics such as ditching, water ponding on or around the road, and evidence of past washouts were used to assess road drainage. As such, a road was given a "NOW" need for drainage if there were evident drainage problems that would likely lead to an impassable road during a heavy rain or a rapid snow melt.

# 2.0 The Road System

#### 2.1 Inventory and Classification

All roads in the Township road system were inventoried according to the methods outlined in the Inventory Manual for Municipal Roads.

The inventory procedure requires that each road in the system be studied as a separate unit. Initially, the road system was divided into sections so that each conformed, as close as possible, to the following requirements:

- Uniform traffic volume.
- Uniform terrain.
- Uniform physical conditions.
- Uniform adjacent land.

Depending on location with respect to the built up areas, roads were classified in a manner generally descriptive of the type of construction as follows:

- Urban Roads with curb and gutter and storm sewer drainage.
- Semi-Urban
   Roads in built up areas (development exceeds 50% of the frontage) without curb and gutter or curb and gutter on one (1) side only.
- Rural Roads with development on less than 50% of the frontage.

Rural roads were further evaluated based on estimated traffic volumes; such as 0 to 50 vehicles per day, 51 to 200, and 201 to 400 etc. For the purpose of this study, traffic volumes were adopted or estimated from traffic counts completed by the Township.

**Table 3** summarizes the total road length in kilometres by surface type and roadenvironment as of November, 2019.

	Township of Hamilton					
Road System in Kilometres						
	(As of November 2019)					
Α.	Surface Type	Totals*				
	Gravel (loose Top Gravel)	31				
	Surface Treatment (LCB & ICB)	145				
	Hot Mix Asphalt (HCB)	123				
	Total A	299 km				
Β.	Roadside Environment					
(i)	Rural					
	Gravel (loose Top Gravel)	31				
	Surface Treatment (LCB & ICB)	144				
	Hot Mix Asphalt (HCB)	80				
(::)	Total Rural	255 km				
(ii)	Semi-Urban					
	Gravel (loose Top Gravel)	<1				
	Surface Treatment (LCB)	1				
	Hot Mix Asphalt (HCB)	36				
	Total Semi-Urban	37 km				
(iii)	Urban					
	Gravel (loose Top Gravel)	0				
	Surface Treatment (LCB)	0				
	Hot Mix Asphalt (HCB)	7				
	<u>Total Urban</u>	7 km				
	Total B	299 km				

#### Table 3 – Road System Inventory

# 3.0 Road Needs

The primary purpose of the study is to develop a list of all roads within the Township ranked according to priority with respect to road needs.

The method of evaluating road needs in terms of type, cost and timing of improvements is identified in the Inventory Manual for Municipal Roads.

It is important to note that budgetary restrictions will often influence the level of upgrades to the road system and therefore it is imperative to maximize the improvements based on availability of funds and needs priority.

#### 3.1 Critical Deficiencies

The inventory of the road system revealed that certain road sections are now deficient or will become deficient during the study period.

As noted previously, critical deficiencies include road characteristics which result in increased maintenance costs and which inevitably lead to an inadequate level of service. A road section is critically deficient if any one of the following characteristics fall below the minimum tolerable standards defined in the Inventory Manual.

•	Surface type	-	Incorrect surface type to suit traffic volumes on the roadway.
•	Surface width	-	Insufficient width of the road surface excluding the shoulders.
•	Capacity	-	Inability of the road to accommodate traffic volumes at peak periods.
•	Structural Adequacy	-	Inability of the road base to support vehicular traffic.

Drainage
 Increased frequency of flooding or excessive
 maintenance effort required to prevent flooding.

Of the 299 km of roads inventoried, a total of 47 km were found to be critically deficient in one (1) or more areas. Of the 47 km, approximately 17 km represents roads with AADT of less than 50 vehicles. Regardless of condition, roads with AADT of fifty (50) or less are typically assigned as "Adequate" (as per the Ministry protocol) for the purpose of the system adequacy calculation.

The overall system adequacy for the Township's road network, which is based upon the total road kilometres less the identified critically deficient ("NOW" needs) roads, is as follows:

2019 System Adequacy = 
$$\frac{299 - (47 - 17)}{299} \times 100\% = 90\%$$

The average surface condition rating of all roads is 7.7/10 while the average structural adequacy rating is 14.8/20. This suggests that the typical road has a fair to good riding quality, but just at the point where significant rehabilitation or reconstruction is required.

As required by O. Reg. 588/17, the average unpaved road was in good condition and the average PCI for hard top surfaces in the Township is 69.9.

A review of the structural adequacy distribution of the Township's hard top roads reveals that over half, 151 km, that are in very good condition (structural adequacy of 15 and over), and with regular resurfacing and preservative maintenance, should not require reconstruction in the next 10 years. Another cohort of roads, approximately 45 km, are in average condition (Structural Adequacy from 12 to 14). Some of these roads may continue to perform well, but without timely resurfacing and preventative maintenance, many of them are expected to become NOW or 1 – 5 year needs. The remaining 72 km of hard top road network is well distributed over the very poor to poor range (structural adequacy from 5 to 11). Most of these roads will require reconstruction over the next 5 years to fully repair them.

It is therefore recommended that, while the Township endeavors to repair these poor roads as part of its 10-year capital plan, every reasonable effort is made, through preservation management, to prevent the current cohort of fair to very good roads (151 km) from becoming capital reconstruction needs themselves.

#### Figure 1 – Structural Adequacy Distribution

#### 3.2 Priority Ratings of Roads

A mathematical empirical formula was used to calculate the priority rating for each road section. The priority rating is a weighted calculation which takes into account the existing traffic volume and overall condition rating of the road.

This priority analysis is an impartial procedure to place the deficiencies in order of relative need. A higher Priority Rating number indicates a relatively greater need for improvement.

The formula takes into account the current traffic volume (AADT), whether it is from actual road counts or estimated road counts and the Condition Rating (CR) of the road at the time of this Road Needs Study Report. The formula is as follows:

#### Priority Rating = $0.2 \times (100 - CR) \times (AADT + 40)^{0.25}$

In utilizing the above equation Wills identified a priority listing for review with Township staff. It is important to emphasize that the priority rating calculation considers only CR and traffic volumes.

When developing the recommended capital expenditure plan consideration may be given to the remaining useful service life of a road / roadbed with a view to coordinating major reconstruction efforts at / near the end of the road's life. Furthermore, while a priority rating will give a general idea of which roads should be improved before others, it does not prescribe an exact order for road improvements nor does it determine the timing of preservation and rehabilitation work. For example, it may be wise to defer the full reconstruction of a high priority road ("let the bad roads fail") in favour of resurfacing work on a medium priority road ("keep the good roads good").

#### 3.3 Dominant Distress Types

As detailed in **Figure 2**, aggregate loss had the highest effect on PCI rating on the Township's HCB network. Transverse and wheel track cracking were also substantial. Flushing, and rippling and shoving were not observed during inspections.

Figure 2 – HCB Distress Type Prevalence

Distress Type

As detailed in **Figure 3** the principal distress types in the Township's LCB and ICB roads were distortion, pavement edge cracking and alligatoring. Potholes, longitudinal cracking and pavement edge break were moderately significant.

Figure 3 – Surface Treated Distress Type Prevalence

Distress descriptions can be found in **Appendix B**.

# 4.0 Roads Best Management Practices

The key to managing a pavement / road network is the timing of maintenance and rehabilitation activities. This idea evolves from the fact that a pavement's structural integrity does not fall constantly with time. A pavement generally provides a constant, acceptable condition for the first part of its service life and then begins to deteriorate very rapidly. In many cases, maintenance and rehabilitation measures are not taken until structural failure or noticeable changes in ride quality become apparent. This is the "fix it once it is already broken" approach.

The unfortunate consequence of this decision is that maintenance and rehabilitation becomes exponentially more expensive over the life of the pavement and is often overlooked until the pavement condition reaches a severe state of distress. There is opportunity for substantial cost savings when intervention is made before the pavement becomes severely compromised; i.e. "fix it before it breaks". **Figure 3** illustrates the underlying principle in support of a preservation management approach to pavement infrastructure. The principle also has application to each of the classes of roads maintained by the Township. Significant cost savings will result from proactive intervention rather than simply waiting as long as possible before performing maintenance.

Examples of approach to roads management with their associated cost implications over the lifecycle of a road are set out below in **Figure 4** and are provided as an illustration of the benefit of a "preservation management approach".

#### Figure 4 – Typical Service Life of an Asphalt Pavement

#### 4.1 Example Life Cycle Cost Analysis

The following life cycle costs analysis compares three (3) different municipalities Municipality 1, Municipality 2 and Municipality 3; each with three (3) distinct approaches to pavement management. For this analysis we will assume each of the three (3) municipalities has 7000 m<sup>2</sup> of pavement, i.e. 1 km of asphalt paved road that is 7 m wide. In each scenario, the road is assumed to have been constructed in 2013 and will operate under normal traffic loading.

The Life Cycle Cost Analysis (LCCA) assumes no user costs. The LCCA uses a discount rate of 2.5% / year.

The LCCA shows the three (3) different municipalities and tracks their pavement management decisions and related condition over the specified time period. <u>Municipality 1</u> represents decisions made based on strategic preventive maintenance and rehabilitation (M&R), <u>Municipality 2</u> represents decisions based on no preventive M&R and <u>Municipality 3</u> represents decisions based on resurfacing only.

Figure 5 below illustrates a time-pavement condition plot for each municipality.

Figure 5 – Time-Condition Plot for 3 Municipalities

	•	· · · ·	Prev	ventive M&R	-		• •				
Year	Age	Treatment	Δ PCI	PCIq	Quantity	Unit	Unit Cost	Total Cost	Present Worth		
		Annual Ditching/Clearing									
2018	5	Localized Preventive - Rout and Seal	81-90	Satisfactory-Good	1000	m	\$1.50	\$1,500.00	\$1,325.78		
2023	10	Global Preventive - Slurry Seal	70-81	Satisfactory-Good	7000	m²	\$6.50	\$45,500.00	\$35,544.53		
		Surface Course									
2033	20	Mill and Dispose of Surface Course	64-100	Poor-Good	7000	m²	\$12.00	\$84,000.00

		Final PCI in 2063:	90	Good				Net:	\$306,967.90		
Residual Value:								\$85,346.08			
								Total Cost:	\$221,621.82		

The costs associated with the corresponding maintenance and rehabilitation decisions are outlined in the following three (3) charts:

The policy of <u>Municipality 1</u> is to strategically intervene with preventative maintenance measures over the course of the pavement's service life. Two (2) significant maintenance measures are performed on the pavement at various times and ultimately extend the service life of the pavement, prorating the total cost of the pavement over a longer period of time. Eventually, a full reconstruction is required and this cycle repeats. The total life cycle costs are substantially less when compared to Municipality 2 and 3, at a total of \$221,622 over 50 years.

			No Pr	eventive M&R

								\$325,937.50	\$104,673.45
		Final PCI in 2063:	86	Good				Net:	\$369,182.56
							Res	sidiual Value:	\$81,552.92
						-		Total Cost:	\$287,629.64

The policy of <u>Municipality 2</u> is to simply construct the pavement and wait until serious deficiencies begin to appear before acting. This approach unfortunately remains common still today. Over the last period of the pavement's life, maintenance is required to ensure safety and operation until the pavement becomes completely destroyed. Once the pavement has failed, a complete reconstruction is carried out restoring the pavement to new condition. This cycle repeats again until a second reconstruction is required. The total costs are substantial and total \$287,630 over 50 years.

The policy of <u>Municipality 3</u> is periodic resurfacing. The pavement is constructed and time passes until early signs of serious distress are observed. This occurs after the time when preventive maintenance is neither appropriate nor possible, but before the pavement becomes completely destroyed. Resurfacing is performed and restores the pavement to almost new condition. The pavement then deteriorates for the remainder of its life, requiring significant maintenance in the last years before it becomes completely destroyed. A full reconstruction is then carried out and the cycle continues. The total costs are in between that of Municipality 1 and 2 at \$260,038 over 50 years.

Resurfacing Only									
Year	Age	Treatment	Δ PCI	PCI <sub>q</sub>	Quantity	Unit	Unit Cost	Total Cost	Present Worth

								\$204,487.50	\$53,898.67
Final PCI in 2063: 66 Good Net:								\$322,624.67	
							Re	sidiual Value:	\$62,587.12
								Total Cost:	\$260,037.55

It may be easy to see upfront cost savings by understanding that as long as any costs associated with maintaining the pavement are deferred as long as possible, money will be saved. The reality is that extending a pavements service life prorates the total cost of the pavement over a longer period of time and ultimately becomes more economical in the long run. If preventive maintenance measures are strategically planned and carried out, then the service life of the pavement can be maximized and substantial reconstruction costs can be deferred for longer periods of time. In a time when economy and efficiency are becoming more and more important, this type of proactive management is essential in the management of infrastructure.

#### 4.1.1 Gravel Roads

The Township currently maintains approximately 31 km of gravel road. The proposed preservation management approach for this class of road is outlined in the following **Table 4** and **Table 5**.

Action	Frequency
Regrade surfaces to maintain smooth / safe driving surface and proper crossfall.	As needed, generally 2-3 times per year for higher volume gravel, or more frequently as necessary; 1-2 for lower volume.
Add calcium to tighten surface, retain aggregate and reduce dust.	Each spring on all roads of higher volume and as needed during summer months.
Ditching and brushing of right-of-ways to improve roadbed drainage and safety.	Complete road network every 10 years.

#### Table 4 – Preservation Management Approach- Gravel Surface

#### Table 5 – Capital Activities – Gravel Roads

Action	Frequency
Add layer (75 mm) of granular material to road surface.	Every 3 years for gravel roads.
Base and sub-base improvements.	As needed or as dictated by traffic volumes.
Reconstruct / convert to hard top.	As dictated by traffic volumes.

#### 4.1.2 Surface Treated Roads

Surface treated roads have a hard wearing surface that must be preserved in order to be effective. The Township currently maintains 145 km of surface treated roads. Unlike gravel roads, a significant investment has been made in the surface and consequently these roads must be managed properly to obtain the longest possible service life from the surface.

Activity	Activity Age (Years) Ride		Estimated Service Life Extension (Years)		
Slurry Seal	3	8	4		
Single Surface Treatment	6	7	3		
Double Surface Treatment	10	6	5		
Pulverize and DST	14	<4	8		

In addition to the noted preservation approach in **Table 6** – Preservation Management Approach – Surface Treated Roads, the following best management practices may be employed to preserve the surface, extend the service life and reduce life cycle costs of surface treated roads:

- 1. Surface treatment shall be applied to the entire road platform, from "grass to grass", including any shoulders. This will eliminate grading on surface treated roads, which has a tendency to damage the edge of the surface treatment and cause premature failure of the surface.
- 2. Suitable new technologies will be utilized where they can be demonstrated to reduce life cycle costs, such as fibre-reinforced surface treatment. This technology can be used to mitigate reflective cracking (if cracks are narrow and inactive) when a single or double surface treatment is applied over an aging surface. It can eliminate the need for pulverizing the underlying surface in certain situations and can reduce overall costs.
- 3. Assess drainage and culvert needs prior to any significant renewal or rehabilitation strategy and complete any improvements concurrently. This will eliminate the need to cut / excavate a relatively new surface to replace a culvert.
- 4. Ditching and clearing (brushing) of the right-of-ways (ROW) to improve roadbed drainage and safety.

#### 4.1.3 Asphalt Roads

Asphalt surfaces are the smoothest and most durable hard top surface used by the Township however; they are also the most expensive. The Township currently maintains 123 km of asphalt surface roads. Asphalt provides a constant, acceptable condition for the initial portion of its service life but then begins to deteriorate rapidly as it ages. Surface defects such as cracking and raveling are the first signs of the deterioration. If left untreated, the pavement will rapidly deteriorate to the point where reconstruction is the only option. A preservation management strategy can mitigate this by applying renewal treatments earlier in the pavements life before the conditions begin to deteriorate too far. **Table 7** below summarizes preservation management activities to be considered for asphalt roads:

Activity	Activity Age (Years)		Estimated Service Life Extension (years)		
Crack seal	2-6	9	2		
Slurry Seal / Microsurface	4-8	8	4-6		
Overlay	12-15	6-7	10		
Pulverize and Pave	20-25	< 5	20		
Reconstruct	30	< 4	30		

 Table 7 – Preservation Management Approach – Rural Asphalt Roads

Note: Slurry seal can be used on lower volume paved roads (less than 1000 vehicles per day). For roads with volumes in excess of 1000 AADT, microsurfacing should be considered.

In addition to the above noted preservation approach, the following best management practices may be employed to extend the service life and reduce life cycle costs of asphalt roads:

- 1. Review the condition of other infrastructure, particularly underground infrastructure prior to implementing any major renewal or rehabilitation of the pavement. Any repairs or capital upgrades to other infrastructure should be coordinated. This should reduce utility cuts in newer asphalt.
- 2. Repair potholes in the surface in a timely fashion to prevent saturation and weakening of road base.
- 3. Undertake regular shouldering program of rural paved roads to promote proper drainage. Poorly maintained shoulders allow surface water to pond and saturate the road base, which weakens the base and leads to cracking at the edge of pavements.
- 4. Undertake a ditching program to ensure there is adequate drainage for road base on rural roads. This will reduce the likelihood of structural distresses caused by softening of the road base due to poor drainage.
- 5. Specify the appropriate type of performance graded asphalt cement for the location.
- 6. Undertake a clearing program to reduce shading of the roadbed and remove roots / vegetation from the road base.

#### 4.2 Application of Preservation Management Approach

The preservation management activities detailed in each of the tables above are not necessarily intended or required to be completed on each and every road. Road deterioration rates and the type of deterioration will dictate when action should be taken and what kind of treatment is most appropriate. The intention of the above is to outline the series of techniques to be considered in an effort to realize and extend the useful service life of the road asset for the lowest overall lifecycle cost while maintaining the highest overall condition. As detailed in the life cycle costs analysis presented above, the preservation management approach to roads is proven to yield the lowest overall life-cycle costs.

Each of the preservation management activities for gravel, surface treatment and asphalt roads identified above (including route and seal, slurry seal, resurfacing etc.), shall be considered as part of the regular Road Needs Study Report every five (5) years. Recommendations on the specific treatments required shall be documented and prioritized in this Report.

#### 4.3 Types of Improvements

All roads were examined to appraise the extent and type of improvement necessary.

"Order of Magnitude" construction costs were developed for each of the below options on a per kilometre basis. An estimated cost for isolated frost heave repairs was also considered.

The below alternative rehabilitation strategies are considered preliminary in nature and are intended to assist in providing an order of magnitude cost estimate to rehabilitate the road. Further field investigations and engineering design is required to confirm and develop the rehabilitation strategies for each road.

#### 4.3.1 Asphalt

High Class Bituminous roads (HCB) or hot mix asphalt roads have rehabilitation alternatives ranging from a simple overlay to complete reconstruction. The following is a listing of standard road rehabilitation techniques that were considered for HCB or hot mix asphalt roads.

- **RO1** Resurfacing, Single-Lift Overlay.
- **RO2** Resurfacing, Double-Lift Overlay.
- **RMP1** Resurfacing, Mill and Pave 1-Lift.
- **RMP2** Resurfacing, Mill and Pave 2-Lifts.
- PP1 Pulverize and Pave 1-Lift.
- PP2 Pulverize and Pave 2-Lifts.
- **Recon 1R** Excavate and Reconstruct Road and Pave 1-Lift Rural.
- **Recon 1S** Excavate and Reconstruct Road and Pave 1-Lift Semi-Urban.
- **Recon 2S** Excavate and Reconstruct Road and Pave 2-Lifts Semi-Urban.
- **Recon 2U** Excavate and Reconstruct Urban Road and Pave 2-Lifts Urban.
- **SS** Slurry Seal (Preventative Maintenance).
- **MS** Microsurfacing (Preventative Maintenance).
- **RS** Route and Seal (Preventative Maintenance).

#### 4.3.2 Surface Treatment

Surface treated roads are generally able to be rehabilitated with either a single or double Low Class Bituminous (LCB) overlay treatment. They may also be upgraded to HCB pavement or downgraded to gravel. In some cases, previous resurfacing of LCB roads has occurred or the LCB surface or road structure has deteriorated to a state where a simple overlay surface treatment is not feasible. In these cases consideration can be given to removal or pulverizing of the existing surface treatment and placement of a new application. In some cases, where it is necessary to improve the overall

roadbed structure, the addition of Granular A to build up the road and the reapplication of a surface treatment is recommended. The following is a listing of standard road rehabilitation techniques that were considered for LCB (surface treated) roads:

- **ST1** Single Surface Treatment.
- **ST2** Double Surface Treatment.
- **ST2R** Double Surface Treatment, with Removal of Existing.
- **ST2A** Double Surface Treatment, over New Granular A.
- **ST2PA** Double Surface Treatment, over Pulverized Existing and New Granular A.
- **ST2PAW** Double Surface Treatment, over Pulverized Existing and New Granular A with 1 m Widening.
- **SS** Slurry Seal (Preventative Maintenance).

#### 4.3.3 Gravel

Gravel roads can likewise be upgraded with the reapplication of Gravel (G) or surface treatments (ST2).

#### 4.4 Benchmark Construction Costs

The Unit Price Form found in **Appendix A** is based on average prices for the local area. The unit prices were used to prepare an array of benchmark construction costs.

The design standards in **Table 8** were utilized for development of the benchmark cost estimates for reconstruction. It should be noted that these are suggested standards and therefore should not necessarily be used as standards for detail design of roadway improvements.

Functional Classification	Surface Width (m)	Shoulder Width (m)	Granular A Depth (mm)	Granular B Depth (mm)	Hot Mix Depth (mm)*
Rural R200 (50 to 199 vpd)	6.0	1.5	150	450	-
Rural R300 (200 to 399 vpd)	6.0	1.5	150	450	16*
Rural R400 (400 to 999 vpd)	6.5	1.5	150	450	50
Semi - Urban Local Residential	6	1.5	150	450	50
Semi - Urban Local Industrial	6.5	1.5	150	450	50
Urban Local Residential	8.5	-	150	600	100
Urban Local Industrial	9.0	-	150	600	100

Table 8 – Design Standards for Construction Cost Estimates
--

Note - Prime and Double Surface Treatment is based on 16 mm of Hot Mix.

# 5.0 Improvement Plan

In the following tables you will find three (3) columns being used to describe the condition of the road; Surface Condition, Structural Adequacy, and Condition Rating. To better understand the prioritization of the lists, descriptions of these ratings can be found below.

**Surface Condition:** Surface conditions relate to driving ease, comfort and safety. Inadequacies for paved surface include excessive or uneven crowns, washboarding, raveling and bumpiness because of cracking, sealing, and rough patching. Inadequacies on loose top surfaces do not include situations that can be readily corrected by maintenance blading. They do include unconsolidated surfaces due to poorly graded or clean aggregate and permanent roughness due to insufficient depth of aggregate or weak subgrade. The effects of surface inadequacies in ascending order of seriousness are noise, vibration, sway, excessive steering effort and reduced speed. *Rated on a scale of 1 to 10*.

**Structural Adequacy:** The Structural Adequacy point rating relates to the capability of the surface and base courses to support a load and to resist deformation or rupture. Soft spots and frost boils are structural adequacy distress signs for loose top roads. For paved surfaces, distress signs may be cracking, rutting, heaving, pot-holing, roughness, alligatoring, dishing, breakup, distortion, frost boils, etc. *Rated on a scale of 1 to 20*.

**Condition Rating:** A holistic rating that sums point ratings from alignment, surface condition, surface width, level of service, structural adequacy, drainage and maintenance demands. The condition rating is one of the major factors used to calculate the Priority Rating. *Rated on a scale of 1 to 100*.

#### 5.1 Road Needs

The Township of Hamilton's Capital Improvement Plan is included on the next page, **Table 9.** This table notes the recommended capital improvements based on priorities throughout the Township. **All costs are based on 2019 dollars and should be adjusted for inflation based on program year, for budgeting purposes.** The capital improvements are listed in descending priority based on traffic volumes and Condition Rating, as described previously.

### Table 9 – Township of Hamilton's Capital Improvement Plan

### \*Listed in 2020 Construction Program

#### Notes:

1. Rehabilitation strategy to be confirmed by geotechnical investigations at detail design.

2. Timing of storm sewer/culvert work should be considered in conjunction with road reconstruction and vice versa, where applicable.

3. Costing is zero for roads within the network but maintained by others (i.e. boundary roads).

### 5.2 Annual Resurfacing Program

Based on typical degradation rates for gravel roads, surface treatment, and hot mix, a resurfacing program / budget is recommended, in addition to the noted capital improvement works, as follows:

### Hot Mix Paved Roads:

- 122.5 km of paved roads (HCB).
- Degradation rate 0.25 / year (rating drops from 10 to 5, over a 20-year period).
- Annual resurfacing 6.1 km / year.
- Annual budget \$1,774,600: (6.1 km / year x \$143,000 / lane km RMP1 x 2 lanes).

### Surface Treated Roads:

- 145.5 km of surface treated roads (LCB & ICB).
- Degradation rate 0.625 / year (rating drops from 10 to 5, over a 7-year period).
- Annual resurfacing 20.8 km / year.
- Annual budget \$436,800 (20.8 km / year x \$21,000 / km \$T1).

Gravel roads require regular maintenance. Maintenance includes regular grading and reapplication of new gravel. Typically, gravel roads should be resurfaced on a 3-5 year cycle.

### <u>Gravel Roads:</u>

- 31.4 km of earth / gravel roads.
- 75 mm gravel every 3 years.
- Annual gravelling of 10.5 km.
- Granular A (\$20,000 / km).
- Annual budget \$210,000 (10.5 km / year x \$20,000 G) \*\*.

\*\* Cost based on supply and application of gravel by external forces.

### The total resurfacing program, (hot mix, surface treatment and gravel) is estimated at \$2,391,400 per year.

Relative road preservation / resurfacing priorities for all roads not included in the previous Capital Improvement Plan are listed below in **Table 10**, Township of Hamilton's Resurfacing Priorities. Roads are listed in order of descending preservation priorities.

#### Notes:

1. Priorities in descending order. The higher the priority rating the greater the need.

Rehabilitation strategy to be confirmed by geotechnical investigations at detail design.
 Costing is zero for roads within the network but maintained by others (i.e. boundary roads).

### 5.3 Preservation Management

Preservation techniques seal the surface as to prevent water infiltration into the granular base. Route and Seal is used on HCB pavements to seal individual cracks. Slurry Seal / Microsurfacing is used on LCB and HCB pavements to seal large areas, although wide / active cracks will reflect through the treatment. An annual preservation management budget has been estimated as follows:

### **Cracksealing**

- 122.5 km of paved roads (HCB).
- Assume that cracksealing will be applied, on average, once per resurfacing cycle.
- Annual cracksealing of 6.1 km / year.
- Annual budget \$24,400 (6.1 km x \$4,000 / km Cracksealing).

### Slurry Seal / Microsurfacing

- 122.5 km of paved roads (HCB).
- 145.5 km of surface treated roads (LCB & ICB).
- Assume that slurry seal / microsurfacing will be applied, on average, once per resurfacing cycle.
- 26.9 km of road to preserve per year (6.1 km HCB and 20.8 km of LCB).
- Annual budget \$570,470(32.5 km x \$20,000 / km Slurry Sealing / Microsurfacing).

### 5.4 Road Maintenance

Preventative road and roadside maintenance is critical to prolonging the useful service life of a road and maximizing the capital investment. A continuous road and roadside maintenance program is recommended to reduce the road degradation rates. Ditch cleanout and clearing of vegetation from the right-of-way should be carried out on a regular basis. This can either be accomplished through dedicated internal Township forces or sub-contracting to private contractors. Consideration may be given to a dedicated capital program of ditch cleanout and clearing, to ensure resources are

### 5.5 Replacement Cost

In conjunction with this Road Needs Study Report, a replacement cost for the road asset was calculated based strictly on roadbed materials i.e. sub-base, base and surface. Road design standards noted in **Table 8** were used to estimate the existing depth of road bed materials for the purpose of the replacement cost calculation.

The total replacement cost for the Township's road infrastructure is approximately \$83.7 M.

Note this cost represents the theoretical road bed materials costs only and does not include items such as removal of the existing road bed, installation of signs, pavement markings, lighting, drainage infrastructure, property etc.

### 6.0 Summary

D.M. Wills Associates (Wills) undertook a review of the Township of Hamilton's (Township) existing road network to assess its physical condition and confirm various road attributes. Data collected as a result of the field review was used to develop a prioritized listing of the road network needs based primarily on condition and traffic volumes.

Wills undertook the field study in October and November of 2019. A visual assessment of each road within the Township was undertaken to assess the current condition of the road.

Two primary indicators of the relative health of a road are the structural adequacy and surface condition ratings. The current average structural adequacy rating for the Township's road network is 14.8/20. The current average surface condition rating for the Township's road network is 7.7/10.

## 6.7% (20 km) of the road network has a Structural "NOW" need, 17.7% (53 km) has a Structural "1-5" year need, and 17.0% (51 km) of the road network has a Structural "6-10" year need.

### Preservation Management

In addition to addressing currently deficient roads (i.e. capital reconstruction), a dedicated preservation management approach is required, <u>and perhaps even more</u> **importantly**, to "keep the good roads good"; the fundamental principle being that it costs much less to maintain a good road than it does to let it fail and then reconstruct it, from a life cycle cost perspective. Ultimately, the goal of preservation management is to extend the useful life of a road and road network, maximizing the municipality's investment over the road life-cycle.

Road resurfacing is an effective way of extending the overall life of the pavement structure and therefore a road resurfacing program is highly recommended. Roads with a structural adequacy of 12/20 or greater are included as candidates for potential resurfacing. Preliminary recommendations and prioritization for road resurfacing are based on condition rating and traffic demands on each road section, as per the Inventory Manual. A road with higher traffic volumes and fair structural adequacy is given priority over a road with moderate traffic and good structural adequacy score, in an attempt to intervene and extend the life of the road before it deteriorates to a level that can no longer be resurfaced (i.e. more expensive reconstruction is required). Specific resurfacing treatment recommendations must be assessed through further field

investigation and detail design effort, prior to selecting and implementing the resurfacing strategy.

## Based on typical degradation rates for gravel roads, surface treatment, and hot mix, a total resurfacing program, (hot mix, surface treatment and gravel) is estimated at \$2,391,400 per year.

Further to the recommendations above with respect to resurfacing, it is also recommended that regular maintenance in the form of roadside ditch cleanout and clearing be undertaken as a critical component to preservation management in order to extend the useful service life of the existing roads.

### Capital Improvements

Preliminary recommendations and prioritization for planned capital improvements i.e. reconstruction, have been developed based on the condition rating and traffic demands on each road section, as per the Inventory Manual. Those roads identified as having a "NOW" or 1 - 5 year need have been included in the capital improvement plan for reconstruction.

A total length of 73 km of roads were identified as having structural needs in the "NOW," or 1 - 5 year periods. The estimated cost to improve these roads is approximately \$ 12.5 M.

The time of inspection plays a significant role in assessing a road's condition. Certain deficiencies, particularly for gravel roads, are only obvious during the "spring break-up" period. By midsummer, any evidence to suggest these deficiencies may have disappeared due to regular grading and grooming activities and general drying of the roadbed. The field work for this study was carried out in October and November 2019, by which time of "spring break-up" was not evident.

We trust the above and attached information will be of benefit to the Township and appreciate the opportunity to assist the Township in developing its road improvement plan.

Respectfully submitted,

A Pince

Eric St. Pierre, P.Eng Transportation Engineer

ESP/ms

### Statement of Limitations

This report has been prepared by D.M. Wills Associates on behalf of the Township of Hamilton. The conclusions and recommendations in this report are based on available background documentation and discussions with applicable Township staff at the time of preparation.

The report is intended to document the 2019 Roads Needs Study Report findings and assist the Township in developing budgetary plans for investment into their road network.

Any use which a third party makes of this report, other than as a Road Needs Study Report is the responsibility of such third parties. D.M. Wills Associates Limited accepts no responsibility for damages, if any, suffered by a third party as a result of decisions made or action taken based on using this report for purposes other than as a summary of the 2019 Road Needs Study Report findings.

## Appendix B

PCI Distress Definitions

### 1.0 Flexible Pavements – Distress Descriptions

Loss of Coarse Aggregates: Pavement surface is breaking up into small pock-marks as coarse aggregate particles are lost from the surface.

**Ravelling**: progressive loss of pavement materials (coarse or fine aggregates, or both) from surface downward results in a pock-marked appearance.

**Segregation:** A construction-related deficiency resulting in areas of the pavement surface having comparatively coarser or finer texture than that of the surrounding surface; a non-uniform distribution of aggregate sizes through the mat.

**Flushing:** The presence of free asphalt cement on the pavement surface. Most likely to occur in the wheel tracks during hot weather.

**Rippling**: Regular transverse undulations in the surface of the pavement, consisting of closely spaced, alternate valleys and crests (Washboard Effect).

**Shoving**: Singular and multiple waves or humps located transversely or longitudinally on the pavement surface.

Wheel Track Rutting: Longitudinal depressions taking the form of a single or double rut in the wheel tracks after repeated load application. Wheel track rutting results from densification and permanent deformation under the load, combined with displacement of pavement materials. Deep ruts are often accompanied by longitudinal cracking in the wheel tracks.

**Distortion:** Any deviation (other than described for rippling, shoving, and rutting) of the pavement surface from its original shape. Generally, distortions result from settlement, slope failure, volume changes due to moisture changes or frost heaving, and from residual effects of frost heaving accumulating after each winter.

Distortion may take the form of dishing, bumps, dips (do not include the bumps associated with cupped or tented cracks), all of which give rise to pitch, roll, and jarring drop in a moving vehicle.

**Longitudinal Wheel-Track Cracking:** Cracks that follow a course approximately parallel to the centre line of the pavement and are situated at or near the centre of the wheel tracks.

**Centreline Cracking:** Crack(s) that run(s) along or near the road centre line.

**Pavement Edge Cracking:** Crack parallel to extending out from the pavement lane edge, and is either a fairly continuous "straight" crack or consists of crescent-shaped cracks in a wave forma-tion. On some thin asphalt surfaces, pavement edge cracking

progressively encroaches onto the outer wheel tracks through the middle of the lane, and may even progress to the centre line.

**Transverse Cracking:** Crack follows a course approximately at right angles to the pavement centre line. Full transverse cracks tend to be regularly spaced along the length of the road, while half transverse and partial transverse occur at shorter, intermediate distances.

**Longitudinal Meander and Mid-lane Cracking:** Crack, usually quite long, that wanders from edge to edge of the pavement, or crack that is usually straight and parallel to the centre line, at or near the middle of the lane. These types of cracks are usually single cracks, but occasionally secondary cracks do develop parallel to them.

**Random / Map Cracking:** Interconnected cracks forming a series of large polygons that resemble a map. The cracking appears to combine transverse and longitudinal cracks.

Alligator Crack: Cracks that form a network of polygon blocks resembling the skin of an alligator.

### 2.0 Surface-Treated Pavements – Distress Descriptions

**Loss of Cover Aggregate:** The whipping off of cover aggregate under traffic from a surface-treated pavement, leaving only the asphalt.

**Streaking:** Alternating lean and heavy lines of asphalt running parallel to the centerline of the road. Sometimes streaking also occurs at right angles to the centerline.

**Flushing:** Free Asphalt migrating upward to the pavement surface. Most likely to occur in the wheels tracks, especially during hot weather.

**Potholes:** Round of irregular shaped holes in pavement; can be unrelated to other surface defects or a direct result of other defects such as alligator cracking, frost boil, etc.

**Pavement Edge Breaks:** Edge breaking occurs with or without cracks.

**Rippling:** Regular transverse undulations in the pavement surface consisting of closely spaced alternate valleys and crests (washboard effect); unevenness of pavement surface caused by traffic action moving surface mat forward, backward or sideways; often accompanied by "flushing".

**Wheel Track Rutting:** Longitudinal depression left in the wheel tracks after repeated load application resulting from compaction and permanent deformation under load, and pavement materials shoving sideways. Deep ruts are often accompanied by longitudinal cracking in the wheel tracks.

**Distortion:** Any deviation of pavement surface from its original shape (other than described for rippling or rutting). Generally, these distortion result from settlement, slope

failure, and volume changes due to moisture and frost heaving accumulating after each winter. The resulting deformation may take the form of dishing, bumps, dips, tenting or stepping at cracks, all of which give rise to pitch, roll and jarring drop in a moving vehicle.

**Longitudinal Cracking:** Cracks follow a course approximately parallel to the direction of travel and are situated at or near the centre of the wheel tracks, centerline, mid-lane, etc.

**Transverse Cracking:** Crack follows a course approximately at right angles to the pavement centerline. Full width transverse cracks tend to be regularly spaced along the length of the road while half width transverse and part transverse cracks occur at shorter intermediate distances.

**Pavement Edge Cracking:** Crack is parallel to and within 300 mm of the pavement edge and is either a straight continuous crack or consists of crescent shaped cracks in a wave formation. Pavement edge cracking will progressively encroach into the outer wheel tracks through the middle of the pavement lane and may even progress right across the centerline.

Alligator Cracking: Cracks forming from a network of multi-sided (polygon) blacks resemble the skin of an alligator.

# **Appendix C** Guiderail Report Memo

PARTNERS IN ENGINEERING Memo

То:	Township of Hamilton
From:	Eric St. Pierre, P.Eng.
Date:	January 13, 2020
Subject:	2019 Guiderail Report Memo

### 1.0 Purpose, Background and Study Method

The Township of Hamilton (Township) retained the services of D.M. Wills Associates Limited (Wills) to map and inventory the Township's existing Guiderail Systems. This memo summarizes activities undertaken for the inventory.

The purpose of this guide rail assessment is to map the ownship's existing safety device network and determine which systems require repair or replacement.

Wills collected the following information for all guiderails to indicate where major repair or replacement is warranted:

- Type.
- Number of missing hardware.
- Mounting height.

• Number of poor posts.

• Embankment slope.

- Length of distressed cables / beams.
- Offset and Recovery Zone.

### 2.0 Mapping

Guiderail locations were mapped using a handheld GPS to mark their ends. All data collected for the Guiderail Inventory is included in the GIS Mapping. For convenience, a table detailing each guiderail system is provided at the end of this memo.

Delineation posts (i.e. 3-CGR posts without the cable) were mapped and included in the inspection, but not rated as guiderail.

2019 Guiderail Report Memo Township of Hamilton Page 2 of 10

### 3.0 Summary of Findings

The Township maintains 124 guiderail systems with a total length of 8.7 km. Both three-cable guiderail (3-CGR) and steel beam guiderail (SBGR) are present.

### 3.1 Condition

Generally, guiderails within the Township were in good condition, with minor maintenance issues noted. Five (5) systems with a total length of 150 m are in poor condition and are recommended for replacement.

### 3.2 Mounting Height

A guiderail's mounting height is integral to its performance during a collision. Too high, and errant vehicles may slip under it. Too low, and an errant vehicle may vault over it.

The mounting height of 3-CGR, as measured from the shoulder to the top cable, is considered acceptable when between 660 and 710 mm.

Typical SBGR mounting height, as measured from the shoulder to the middle of the rail, is considered acceptable when between 53 0mm to 580 mm. In the last few years, a new "Type-M" standard has been developed for SBGR installations in Ontario. The main difference between Type-M SBGR and pre-Type-M SBGR is placing rail splices between posts as opposed to on them, and a higher mounting height. Type-M SBGR mounting is considered acceptable when between 600 to 650 mm.

Although the physical condition of the guiderail was generally good, over half of the guiderail network was mounted at the wrong height.

- 2,210 m of 3-CGR were mounted too high.
- 950 m of 3-CGR were mounted too low.
- 650 m of SBGR were mounted too high, even when compared to the higher Type-M standard.
- 820 m of SBGR were mounted too low, even when compared to the lower pre-Type-M standard.

2019 Guiderail Report Memo Township of Hamilton Page 3 of 10

### 4.0 Recommendations

All systems in poor condition should be replaced. The protected hazards should be reviewed and lengths of need recalculated for the new installation. Alternative treatments such as slope flattening may be considered in lieu of a new guiderail.

All guiderails should be corrected to their proper height. Given the high percentage of systems with improper mounting heights, the Township should also increase its inspection frequency and consider guiderail adjustment whenever road work is done.
